

Dr Maria Isabel Covas, *Cardiovascular Risk and Nutrition Research Group, IMIM-Institut de Rebeca Hospital del Mar, Barcelona, Spain* ...invited to present all clinical evidences about olive oil polyphenols in [Paris Polyphenol 2012 World Congress](#)

!

It is currently well established that oxidized LDL cholesterol play a major role to initiate the developpment of atheromatous plaques, which are very included in risk of heart attack and many others cardivascular diseases.

One of the earliest steps in generation of oxidized LDL is the peroxydation of its polyunsaturated fatty acids. This situation creates covalent bonds with others molecules such as apolipoprotein B which becomes immunogenic. As a consequence, oxidized LDL antibodies (OLAB) are generated to reduce levels of oxidized LDL and therefore, play a protective role for atherosclerosis.

In clinical European studies, the researcher team of Maria Isabel Covas demonstrates that *“a regular daily dose of olive oil, similar to the daily consumption recommended by the US Food and Drug Administration, increased OLAB plasma concentrations in a dose-dependent manner as the olive oil phenolic compounds increased*

”.
